Automatic Selection of Suitable Sentences for Language Learning Exercises

Ildikó Pilán¹, Elena Volodina², and Richard Johansson³

Abstract. In our study we investigated second and foreign language (L2) sentence readability, an area little explored so far in the case of several languages, including Swedish. The outcome of our research consists of two methods for sentence selection from native language corpora based on Natural Language Processing (NLP) and machine learning (ML) techniques. The two approaches have been made available online within Lärka, an Intelligent CALL (ICALL) platform offering activities for language learners and students of linguistics. Such an automatic selection of suitable sentences can be valuable for L2 teachers during the creation of new teaching materials, for L2 students who look for additional self-study exercises as well as for lexicographers in search of example sentences to illustrate the meaning of a vocabulary item. Members from all these potential user groups evaluated our methods and found the majority of the sentences selected suitable for L2 learning purposes.

Keywords: sentence readability, Swedish, NLP, ICALL, CEFR, GDEX, retrieval, machine learning, supervised classification, corpus-based evidence.

1. Introduction

Native language (L1) texts are a valuable source of authentic sentences suitable for the purposes of L2 learning, either as exercise items or as examples illustrating the meaning of a word. Before being able to use such sentences in CALL systems, however, we have to ensure that these examples are readable, i.e. understandable

by learners both lexically and structurally. Identifying these sentences manually would require a considerable amount of time. Instead, we propose two automatized selection methods which perform this task for Swedish. Both approaches have been integrated into the online ICALL platform Lärka (Volodina, Borin, Loftsson, Arnbjörnsdóttir, & Leifsson, 2012) as part of a sentence readability module called HitEx (Hitta Exempel [Find Examples] or Hit Examples). The selection is based on a number of linguistic factors which were found influential for L2 readability, as well as principles of Good Dictionary Examples (GDEX) (Husák, 2008; Kilgarriff, Husák, McAdam, Rundell, & Rychlý, 2008). The sentences selected by the current version of the system have been evaluated by L2 Swedish teachers, learners and linguists, who provided us with positive feedback.

2. Materials and method

The materials used throughout the study included Swedish native language corpora of various genres (novels, newspapers and blog texts) which are accessible through an online tool called Korp (Borin, Forsberg, & Roxendal, 2012). Korp offers annotations at different linguistic levels for each sentence including parts of speech (POS), morphosyntactic and syntactic (dependency) relations, which have all been exploited in our selection methods. Furthermore, we employed the scale described in the Common European Framework of Reference for Languages (CEFR) when distinguishing L2 difficulty levels. Besides native language corpora, we also utilized the CEFR corpus (Volodina, Pijetlović, Pilán, & Johansson Kokkinakis, 2013), a collection of L2 Swedish materials currently under development, and the Kelly-list (Volodina & Johansson Kokkinakis, 2012), a frequency-based word list with CEFR levels for each item. The platform Lärka, besides the HitEx module in which our selection methods have been incorporated, also includes an exercise generator module (Volodina et al., 2013).

The material described above served as basis for our two selection methods: a rule-based and a combined approach using rules as well as ML techniques. As a starting point, we used an algorithm described in Volodina, Johansson, and Johansson Kokkinakis (2012) based on four selection criteria. This initial set of rules was extended with additions from the GDEX literature (Kilgarriff et al. 2008; Husák, 2008), as well as sentence selection research in the L2 context (Segler, 2007) and readability studies for L1 Swedish (Heimann Mühlenbock, 2013; Sjöholm, 2012). The ML method used in the combined approach consisted of supervised classification, a process in which our model learned to predict whether a sentence is understandable at B1 (intermediate) proficiency level or not, based on training examples from the CEFR corpus and native language corpora. The classification
algorithm employed was a Support Vector Machine (SVM) classifier which aimed at finding a line separating the two classes in the training data (within and above B1 level) based on the linguistic characteristics (features) of each sentence. A visual representation of this idea is presented in Figure 1 below.

Once trained, the SVM tried to place previously unseen sentences from L1 corpora into the right class. The accuracy of the classifier expresses what percentage of these classifications were correct.

3. **HitEx: the L2 sentence readability module**

Through the graphical user interface of the HitEx module in Lärka a number of search criteria for the selection of sentences can be set. Figure 2 illustrates part of this page.

Automatic Selection of Suitable Sentences for Language Learning Exercises

On the left hand side 26 selection criteria, or *parameters*, are listed (only part of these are visible in Figure 2), grouped in three categories: general, structural and lexical. General parameters include basic information about the sentences to select, namely the word to search for (*keyword*), its POS, the corpora from where to choose the examples, etc. Through structural parameters morphosyntactic preferences can be defined. These consist of parameters such as average sentence and word length, percentage of relative pronouns as well as the optional avoidance of participles and modal verbs.

Finally, lexical parameters contain the avoidance of proper names, the allowed percentage of words above the selected CEFR level, etc. Each parameter value can be associated with a *penalty score*, determining the final *ranking* of the sentences based on how well they satisfy the search criteria. A predefined setting is currently available for levels B1, B2, C1+, together with a setting for lexicographers (GDEX). As the presence of the two columns for the parameter values indicates in Figure 2, it is also possible to experiment with two different settings simultaneously.

Instead of using only parameters, the ML component, which we called LäSAS (Lätt/Läs Svenska som Andra Språk [Easy / Read Swedish as a Second Language]), can be selected to be used in combination with some of the parameters. LäSAS classifies sentences based on a large number of linguistic features such as the average number of senses per word, the frequency and CEFR level of words and aspects of syntactic complexity. Such features are based on Swedish L1 readability studies (Heimann Mühlenbock, 2013; Sjöholm, 2012), L2 readability research for other languages (François & Fairon, 2012; Vajjala & Meurers, 2012) and CEFR based course book syllabuses (Levy Scherrer & Lindemalm, 2009). Currently, LäSAS can determine with 70% accuracy whether a sentence is understandable at B1 level or not.

Figure 3 below presents the structure of the readability module and the process of sentence selection. Once users provide their preferences through the dedicated web page in Lärka, the corpus tool, Korp, searches for sentences containing the keyword in Swedish L1 texts. In the next step, sentences undergo a selection with the method previously chosen by the user, which is either purely based on parameters or is a combination of parameters and ML classification with LäSAS. Finally, the resulting filtered set of sentences is displayed on the web page where they can be edited and downloaded to a file. The sentence selection methods are also available as a web service, thus they can be easily integrated in other applications.
4. Evaluation

To verify whether the sentences selected by our systems are suitable for L2 learning purposes, we carried out an evaluation with altogether 34 participants, including L2 Swedish teachers, students and linguists (including one lexicographer). The respondents had to evaluate a list of 196 sentences chosen with our two selection approaches. Students were required to tell us whether they understood the sentences, whilst teachers and linguists needed to decide whether, according to their judgements, B1 learners would comprehend the sentences. Altogether 73% of the presented items were considered understandable. There was, however, a significant difference among the percentages of understandable examples according to the subgroup of respondents. Figure 4 below shows this discrepancy.

Teachers were considerably stricter than linguists when judging understandability, regarding 17% fewer sentences acceptable. The first subgroup of learners (adults with university-level education) understood 10% more sentences than students above 16 years with mixed educational background (Students2) and 34% more than 15-year-old high-school students (Students3). Learners understood overall 69% of the examples, 4% more than teachers predicted.
Besides the aspect of understandability, teachers and linguists were also asked to decide whether the sentences would be suitable as exercise items or as examples for vocabulary illustration. About six out of ten sentences corresponded to these criteria. For all three aspects investigated, the purely rule-based approach was slightly preferred (by 3%) to the combined method.

Figure 4. Percentage of understandable sentences per respondent subgroup

During the evaluation, qualitative data has also been collected, which consisted of respondents’ comments about difficult or undesirable elements in the sentences. These included, for example, atypical word order, subordinates and the presence of infrequent idioms. Moreover, the lack of sufficient amount of context, informal spelling and a preference for illustrating the most frequent usage of a word have also been mentioned.

5. Conclusions

We proposed two methods for the selection of sentences from native language corpora which are suitable for L2 learning purposes. According to the results of an empirical evaluation, the approach based only on parameters was somewhat more successful than the one combining rules and ML techniques. The results are encouraging, about 70% of the sentences proved to be of an appropriate level of difficulty. About 10% less were suitable as exercise items and example sentences for vocabulary item illustration. The selection methods found their practical application in an ICALL platform in exercise generation and they are also available as a web service. In the future, we intend to extend the selection to all CEFR levels and we also plan to refine the methods further in attempt to improve the suitability of the sentences chosen.

Acknowledgements. We would like to thank all the linguists, teachers and students who completed our evaluation. We also wish to express our appreciation
to the publishing house Liber for making available materials in electronic format for our study.
